Abstract

As generative AI gains traction in creative industries such as fashion and the furniture industry, the need arises for systematic models that support quality assessment and the improvement of AI-generated outputs. This article introduces the AI Rocket model as an iterative framework where the designer, in close interaction with AI, evaluates, dissects, and further develops the output through a structured process. The article explains the structure and function of the model, illustrates its use with an example from the fashion industry, and discusses its implications for creative practice and design education.

Keywords: generative AI, co-design, iterative design processes, fashion innovation, evaluation, AI-augmented creativity

1. Introduction

The use of generative AI in the design field challenges traditional processes and the division of roles between designer and tool. Where AI was previously considered a supplement to idea generation, today it increasingly acts as a *co-creator,* generating visual expressions, texts, and even complete collection presentations. In this new practice, the need arises for a methodical approach to assessing and refining the outputs generated by AI. The AI Rocket model has been developed with this purpose in mind.

The model offers a structured process where the designer – via the Validation, *Dissection* and *Co-creation* phases – collaborates with the AI to bring the design from problem definition to meaningful solution. The article presents the model, relates it to existing design theory, and shows its practical applicability through an example of developing an AI-generated fashion collection.

2. Model basis: AI Rocket as a design framework

This section establishes the theoretical platform for the proposed model and sheds light on design as a practice of cognition.

2.1. Theoretical framework

The AI Rocket model is rooted in the special epistemology of the design profession, where creative cognition and reflexive practice are given higher weight than methodological unambiguity. This chapter draws in particular on Nigel Cross' concept *of designerly ways of knowing* (2006), Donald Schön's concept of reflection (1983) and Richard Buchanan's analysis of design as a discipline for dealing with complex, unstructured issues (Buchanan, 1992). These theoretical perspectives form the basis for understanding the AI Rocket model as a practice framework in a complex, iterative, and aesthetically grounded design practice.

Cross (2006) argues that design contains a special kind of knowledge that cannot be reduced to natural science or humanistic forms of cognition. *Designerly ways of knowing* denotes a practice-oriented, solution-oriented and artefact-centred approach to knowledge, where the designer creates meaning through material, form and function. The AI Rocket model builds on this understanding by seeing the interaction with AI as an extension of the designer's reflective practice. In this view, AI's generative output does not become a solution, but a catalyst for continued design recognition.

Buchanan (1992) describes design problems as "wicked problems" – characterised by ambiguity, contextual dependency, and multifaceted stakeholders – making them difficult to solve through linear or technically-oriented methods. In an AI context, this type of problem becomes particularly evident, as AI's outputs are often unpredictable and situational. The AI Rocket model addresses this by providing a structure to continuously reformulate, evaluate, and further evolve the problem as new inputs and outputs emerge. In this way, the designer is part of a continuous framing process, where AI not only provides answers but also provokes reflection and new design questions.

Donald A. Schön's (1983) concept *of reflection-in-action* constitutes an essential theoretical pillar for the iterative structure of the AI Rocket model. Where Cross emphasises design as a special form of cognition, and Buchanan emphasises it as an approach to "wicked problems", Schön provides a deeper understanding of how designers actually work with complex and unstable situations: by having a *reflective conversation with the material*.

In AI Rockellen, this is actualised in the interaction between the designer and the AI system's output. When AI generates proposals that either break with the brief, open up new aesthetic possibilities, or fail in semantic clarity, it requires the designer to reflect **in action** – assessing, adjusting, and experimenting in real time. The validation and dissection phases of the model are not neutral evaluations, but design approaches, where the designer negotiates between intent, context and artefact.

Schön's point is that professional practice – including design – is not primarily about applying generalised knowledge to a problem, but about **constructing the problem through action**. This thinking mirrors the model's use of AI as a dialogue partner: the AI's output acts as a mirror and a material that the designer "responds" to – not just with new input, but with a sharpened understanding of the task.

This understanding legitimises the AI Rocket model as a tool that structures the iterative cognition process, in which the AI generates artefacts and the designer evaluates them through his professional judgment. Where models such as design science seek standardised processes, AI Rocket places itself in the tradition *of the science of design* (Cross, 2006) – i.e. the study and development of design as a reflexive practice rather than a linear method. The model

thus offers a framework where man and machine are part of a distributed design community based on aesthetic assessment, context understanding and iterative testing.

2.2 Iterative design processes in an AI context
Iterative design is a cornerstone of design research and is characterised by cyclical processes in which solutions are continuously tested, evaluated and refined (Cross, 2006; Buchanan, 1992). This approach differs from linear development models by emphasising reflection and learning in the process rather than considering design as a one-time delivery. That is, the process logic is cyclical. Models such as IDEO's design thinking and the Double Diamond model from the Design Council build on precisely this thinking, where phases such as 'testing' and 'refining' are not just final steps, but ongoing practice.

The AI Rocket model continues and expands on this tradition by incorporating AI as an iterative co-creator. Iteration occurs not only in the collaboration between humans, but in the reflexive loop between man and machine. AI generates variations, the designer evaluates them and adjusts inputs, and this cycle repeats with gradually increasing precision and conceptual acuity. This means that iteration is not just a practical necessity, but a realisation strategy where the designer gradually clarifies both the problem and the solution through material interaction with the AI system.

In AI-driven design processes, this means that AI-generated output is not only considered as a proposal, but as a dialogical input that can challenge and nuance the designer's assumptions. Here, iteration becomes both a technological feedback mechanism and an aesthetic exploration, where the machine's variations mirror and reinforce human creative intuition. The iterative loop of the AI Rocket model makes it possible to deal with unpredictability, discover alternative solutions and train the designer in what Schön calls *reflection-in-action*. Duan et al. (2024) show just how iterative feedback loops between humans and AI – through visual prompts and ongoing refinement – can qualify design output and strengthen aesthetic alignment.

2.3 Situated agency and human-machine co-creation
Lucy Suchman's (1987) theory of *situated agency* provides an important counterweight to the notion of technological determinism. She argues that meaningful actions do not arise from predetermined plans or linear intentions, but in the situated interaction between actors and their context. Transferred to design with AI, this means that value creation and decisions are not solely the result of human intentions or technological capabilities, but something that *emerges* in the meeting between user, system and situation.

The AI Rocket model activates this understanding by structuring a design process in which humans and machines continuously influence each other's outputs and interpretations. The Validation and Dissection phases function not only as checkpoints, but as arenas for mutual adaptation: AI provides outputs that the designer's aesthetic and contextual judgement processes, and this assessment is in turn shaped by the AI's suggestions and unexpected variations. Thus, a *distributed creativity arises*, where no actor alone controls the process, but where agency is exercised in relation.

In this view, the designer does not become a user of AI, but a *co-creator* in a dynamic ecosystem. The AI Rocket model contains a conscious architecture where decision-making power is shared, and where the designer's task is not only to choose, but to *interpret and co-shape* what AI contributes. This supports an epistemological approach in which knowledge and value are not pre-empted, but arise through negotiation between system and human – a key principle of situated agent theory.

By incorporating this perspective, the AI Rocket model promotes not only efficiency or output quality, but the ability to develop *relational creativity*: the ability to create in dialogue with the unpredictable and to understand design as a continuous negotiation rather than as a sequential production.

2.4 AI-augmented creativity and aesthetic reflection

The concept of *AI-augmented creativity* denotes an approach in which artificial intelligence is not only used as an effective tool, but as a co-creative agency that expands the human scope for idea development, aesthetic experimentation and reflection (Candy & Bilda, 2009). Instead of replacing the human creator, AI acts as a catalyst for new ways of thinking, variations, and unforeseen juxtapositions.

In the AI Rocket model, this manifests itself through the use of generative prompts and feedback loops. The designer formulates an input (textual or visual), the AI responds with an output, and this output is judged not only on the basis of correctness, but on its *aesthetic potential and reflexive value*. It becomes a space for realisation – not just production. When an output deviates from expectations, it becomes an opportunity to reconsider the brief, taste, context and intention, which corresponds to Schön's reflection-in-action.

Therefore, the AI Rocket model is more than a technical workflow – it is a framework for *aesthetic dialogue*. The output from AI acts as a mirror and counterpoint, where the designer must ask questions such as: What evokes this expression? What idiom is in play here? Does it match the brand's DNA? These questions point beyond formal validation and into the domain where the designer mobilises his or her experience, intuition and visual judgment.

In addition, the model activates what could be called *creative prompt literacy* – the ability to control and experiment with inputs in the tension field between control and openness. This skill is essential in AI-enabled design and allows the designer to balance between strategic design and improvisation.

Thus, AI Rocket supports not only creativity in a quantitative sense (more ideas faster), but *qualitatively reflexive creativity* – where output is not simply accepted or rejected, but used to nuance the understanding of both task and aesthetics. This is where AI becomes an actual co-creator. This perspective is an extension of Shneiderman's (2007) work with *Creativity Support Tools*, where technology is designed to promote reflexive, user-centred innovation in creative processes.

2.5 Computational co-creativity and distributed intelligence

According to McCormack et al. (2019) and Yannakakis & Togelius (2014), computational co-creativity denotes an approach in which both man and machine are actively involved in the creative process – not as a hierarchically divided system, but as a mutually dependent production relation. In this view, AI is not just a functional component or passive generator, but an actor that – within its algorithmic framework – contributes its own patterns, suggestions and transformations that humans must relate to reflexively.

The AI Rocket model operates explicitly from this understanding. It does not position AI as an extension of human intention alone, but as an *independent creative agency* whose output can evoke new ideas, disrupt expectations, and propose aesthetic solutions that the designer would not necessarily have come up with himself. This is precisely why the model includes phases such as Dissection and Co-creation: here, AI's contribution must not only be evaluated,

but analysed, selected and transformed in close interaction with human assessments and strategic goals.

This distributed creative intelligence requires a new understanding of design authority. Where previous models often started from a one-pronged creative line – from brief to solution – AI Rocket works with a network of iterations where proposals do not have one origin, but are the result of an ongoing negotiation between the system's variation and the designer's judgement. It creates the opportunity for *emergent design*, where ideas arise through unpredictable interactions between actors.

At the same time, co-creativity opens up for a more pluralistic approach to aesthetics and innovation. The AI can draw on broader visual and semantic references than humans have access to, which can potentially push the design in new directions and provoke *creative divergence* (Rezwana & Maher, 2022). The designer thus gains access to a *creative second-hand thinking*, where AI acts as both sender and reaction space – a partner, not an assistant.

By embedding *computational co-creativity* as a basic premise, the AI Rocket model offers a process architecture that supports the complexity and polyphony that characterise contemporary design tasks – especially in aesthetically and culturally sensitive fields such as fashion.

2.6 Epistemic partnership and creative intelligence

As artificial intelligence (AI) is integrated into creative practices, there is growing interest in understanding the interaction between man and machine as an *epistemic partnership*. In this perspective, AI is not just seen as an external generator or technical assistant, but as a co-creative actor in the development of new knowledge and aesthetic decisions. Haase and Pokutta (2024) highlight how such partnerships can enable breakthroughs in complex design problems, as AI contributes unexpected suggestions and alternative problem formulations that humans can reflect on and further develop.

The AI Rocket model supports this interaction by structuring the design process as an iterative dialogue between actors. The designer provides input, AI generates output, and through phases such as Validation and Dissection, a reflexive cycle arises in which both parties' contributions mutually inform each other. This creates fertile ground for *distributed creative intelligence*, where knowledge and decision-making power are neither centralised in the human being nor in the system, but arise in the dynamics between them.

This approach requires the designer to develop new skills – including prompt literacy, visual analytical sense, and the ability to navigate semi-autonomous design proposals. The AI Rocket model can thus be seen as a framework for training and unfolding *creative intelligence*, understood as a combination of aesthetic judgement and technological resonance sensitivity in a co-creative context.

By operating within this partnership framework, the AI Rocket model legitimises a new way of thinking about creative practice – where innovation is not about devising solutions in isolation, but about engaging in an epistemological conversation with a co-creative machine.

2.7 Design as a material in the context of AI

One perspective that can broaden the understanding of the designer's role in AI collaboration is the idea of design as a form of material practice. Dove et al. (2017) argue that machine learning is not just a technological tool, but a design material in its own right – with specific affordances,

limitations, and behaviours. This requires the designer to take an experimental and reflexive approach to the technology in the same way as they would with physical materials such as fabric, wood or glass.

The AI Rocket model contains just such material thinking in its iterative structure. By repeatedly adjusting prompts, assessing outputs, and changing input formats, the designer works with AI as a living, responsive material. This requires a form of *material literacy* where the designer develops a sensitivity to how small changes in input create different aesthetic, semantic and functional variations in output.

It is especially in the Dissection and Co-creation phases that this material perspective becomes clear. Here, AI outputs are not just analysed as finished proposals, but as raw material that can be processed, combined and further designed. Dove et al. (2017) point out that this requires a new kind of design practice, where learning takes place through direct manipulation and testing – and where the designer builds experience with the AI system's behaviour over time.

By considering AI as material, the AI Rocket model supports a design form that is situated, experimental, and cognitive. This strengthens the model's relevance in creative subjects, where it is not algorithmic precision, but aesthetic sensitivity and the production of meaning that are at the centre.

3. Model Description: AI Rocket as a Design Framework

Based on the theoretical framework, the AI Rocket model operationalises the above-mentioned theories in a practice-oriented design framework.

The AI Rocket model has been developed as a practice-oriented and iterative framework to structure and qualify the collaboration between human designers and generative AI in creative design processes. Where traditional models focus on either linear idea development or technical optimisation, AI Rocket offers a *co-creative process architecture* where both human and machine are included as cognitive actors.

The model consists of seven phases organised in a circular process that can be repeated and varied depending on context, level of ambition and user feedback. The phases are:

1. **Problem definition**
   Determination of the task's purpose, target group, functional requirements and aesthetic objectives. This stage creates the basis for both prompt design and assessment criteria.
2. **Input (Prompting)**
   The designer formulates an input in the form of text, image or a combination thereof, which is communicated to the AI. It can be open and experimental or precise and controlling – depending on the strategy.
3. **The output**
   AI generates suggestions based on the prompt. The results can be visual (images, sketches), textual (product descriptions, narratives), or combined artifacts.
4. **Validation**
   Output is assessed on the basis of brief, aesthetic relevance, technical quality, cultural context and user considerations. Here, the designer's professional judgement is activated in interaction with user feedback and possibly automated evaluations.

5. **Dissection**
   Selected proposals are analysed and broken down into sub-components (shape, colour, silhouette, message). The goal is to identify which sub-elements work – and why. The phase allows for recombination and adjustment.
6. **Co-creation**
   The designer interacts with AI in a co-creative process, where selected fragments are built on. This may involve remixing, new prompting, technical drawings, narrative expansion, or visualisation of details.
7. **Solution**
   The result is a finished artifact – or a conceptually strong proposal – that is based on several iterations and critical selection. The solution can be the end product or a new starting point in a new iteration.

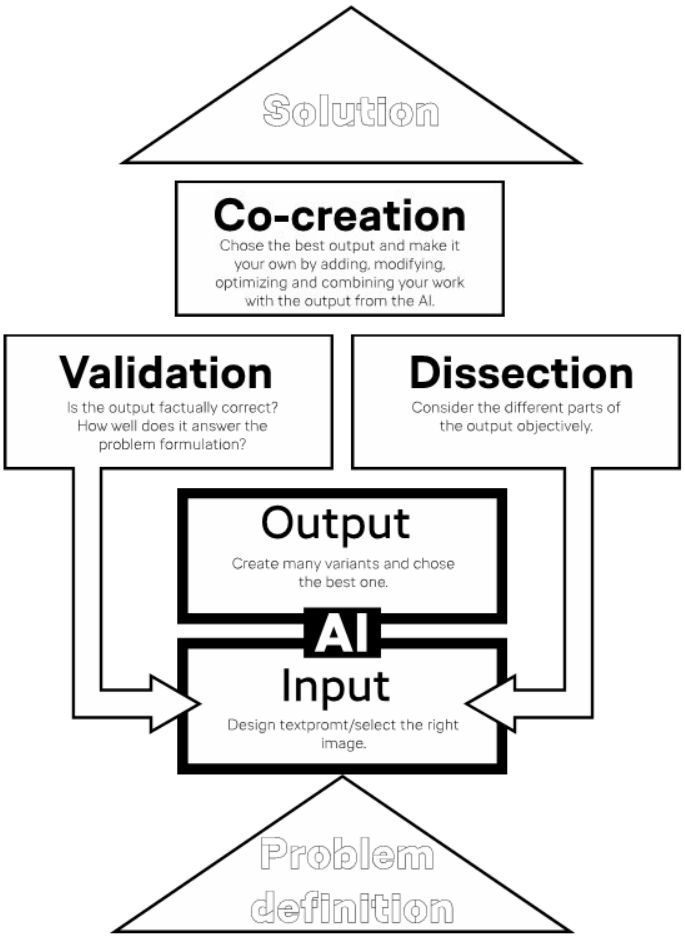

Figure 1. AI Rocket – Iterative design model for AI-generated outputs. Own manufacturing.

The model is explicitly based on *reflection-in-action* (Schön, 1983) and on Cross' understanding of design as a *designerly way of knowing*. By combining iteration, validation, and analysis, AI Rocket creates a systematic yet flexible framework where the designer can navigate complexity, experiment with prompts, and engage in an epistemological partnership with the technology.

At the same time, the model is suitable for teaching use, as it makes visible the decision points and reflection zones that students must learn to master in AI-supported design. It can thus

function both as a design tactical tool and as didactic scaffolding in creative learning environments.

4. Case: An AI-generated capsule collection

To illustrate how the AI Rocket model can be applied in practice, a *fictitious case* about the development of a capsule collection in the fashion industry is presented here. The case is constructed to demonstrate the phases and potential of the model in a creative design process and should be read as a hypothetical process rather than an actual investigation.

Concept and design brief:
A designer works to develop a sustainable capsule collection for young adults aged 18–28. The collection will unite 90s aesthetics with contemporary materials and highlight comfort, recognizability and visual identity. The brief includes a focus on oversized silhouettes, retro logos, organic textiles and gender-neutral design language.

Phases 1–3: Problem Definition, Input, and Output
The designer formulates a prompt for a generative AI tool (e.g., Midjourney or ChatGPT) that specifies the target audience, color palette (dusty rose, khaki, black), material preferences (deadstock denim and GOTS-certified cotton), and aesthetic references (90s hip-hop and minimalist typography). The AI generates 12 visual suggestions with accompanying text descriptions. The results vary in level of detail, creative originality and coherence with the brief.

Phase 4: Validation
The designer assesses the outputs with a focus on aesthetic quality, functionality, and brief alignment. Three proposals are considered relevant: one with a cropped hoodie and an abstract print, one with an oversized denim jacket and one with a graphic typographic element. The rest are discarded due to stylistic incoherence, superficial symbolism or material inconsistencies (Lee & Kim, 2024).

Phase 5: Dissection
The three selected proposals are broken down into sub-components – silhouette, colour scheme, textile structure, and visual balance. The AI's contribution is analysed using image tags and compared with brand DNA and existing mood boards. A print from one suggestion is combined with a colour combination from another. The designer maps out which elements can be reused in the next iteration (Sun et al., 2023).

Phase 6: Co-creation
By re-prompting the AI with modified inputs and by supplementing with their own sketches, the designer puts together new concepts where AI is used to generate variants and perspectives (e.g. back and close-ups, fabric texture, styling scenarios). At the same time, a text-based AI (e.g. ChatGPT) is used to develop storytelling elements and descriptions for campaign materials and lookbooks (Shin et al., 2024).

Phase 7: Solution
The result is a fictional capsule collection consisting of six carefully selected styles that balance AI-generated content with human aesthetic control. The collection demonstrates how the AI Rocket model can be used to structure experimental and co-creative design processes, while also activating critical reflection and selection.

The case illustrates how the AI Rocket model not only organises the design process but also activates an experimental, reflexive, and strategic way of working. The iteration between human judgment and machine generative capacity creates fertile ground for original, purposeful, and aesthetically strong outputs.

5. Discussion: Design strategic potential

The AI Rocket model offers a systematic yet flexible framework for working with generative AI in design processes, where both technological innovation and aesthetic judgement are in play. The fictitious case shows how the model can be operationalised in practice, but its potential extends beyond specific design processes and points towards a new approach to creative practice, where human and machine intelligence co-create in iterative loops.

From a design strategy perspective, the model addresses a key challenge in contemporary AI-supported design: how to ensure qualitative control and meaningful direction when output is generated by a machine. By integrating reflexive phases (Validation and Dissection) between the generation and completion of artefacts, AI Rocket puts structure to what Schön (1983) called "reflection-in-action" – an ongoing, situated negotiation between intuition, material, and context.

In addition, the model makes visible a new division of roles in the design work. The designer no longer becomes a sole inventive actor, but a curative and dialogical co-creator who negotiates with the system's proposals and steers direction through iteration. This changes design competence from primarily being idea generation to increasingly being the ability to assess, select and further develop in collaboration with a non-human partner.

The model also has clear pedagogical qualities. In educational contexts, it can be used to structure AI-driven design projects so that students learn to balance creative freedom and critical reflection. It not only makes the process visible, but also the cognitive choices that lie in designing with AI – and thus not only develops skills in prompting and tool use, but also a critical understanding of form and aesthetic judgement.

Finally, the model enables rapid idea development and concept testing without necessarily compromising design quality – a significant advantage in fields such as fashion, where both time pressure and cultural relevance are crucial (Lee & Kim, 2024). In other words, the model creates space for working creatively and strategically under complex and changeable conditions.

However, it should also be mentioned that the model assumes a certain level of reflection on the part of the user. It is not a recipe, but a framework that requires the designer to actively engage in evaluation, curation, and decision-making. In the hands of less experienced users, the model may therefore risk becoming a mechanical checklist unless it is used in a context that supports critical thinking.

6. Perspectives: Towards a New Design Practice

The AI Rocket model represents a new take on how to structure co-creative processes between humans and AI in design practice. Its iterative, reflexive and cognition-oriented structure makes it suitable for both professional use and teaching, but the model also contains significant development potential that calls for further research and adaptation.

An important perspective is about integrating *automated feedback mechanisms* into the model. For example, user-based preferences, A/B test results, or sentiment analysis can continuously inform the validation phase and complement the manual assessment. This will strengthen the model's applicability in commercial contexts and make it more *data-informed* without losing the aesthetically reflexive aspect.

Another development track is *industry-oriented adaptation*. Although the model here is demonstrated in a fashion context, it also has relevance in related design areas such as graphic design, interaction design, product development and architecture. Common to these fields is the need to balance function, aesthetics and user understanding in a complex, digitalised reality. Adaptation could involve adjusting validation criteria, different types of prompts or industry-specific analysis tools in the dissect phase.

There is also a need to examine the *social and ethical dimensions of the model*. How to deal with bias in AI-generated output? Who owns the co-created work? And how is inclusion and diversity ensured in the data and design choices on which the model is based? These questions open up for both research and normative further development, especially if the model is to be integrated into practice-oriented teaching courses or organisational design processes.

Finally, the model can serve as a platform for *experimental design research*, where different variants are tested and evaluated in authentic processes – e.g. through collaboration with companies, design schools or culture-based actors. Here, the model can function as both a method, an analysis tool and a pedagogical framework, and contribute to strengthening the design field's understanding of how artificial intelligence transforms the ways we create.

7. Conclusion

This article has introduced the AI Rocket model as an iterative and reflexive framework for evaluating and improving AI-generated outputs in creative design processes. Based on both practice and theory, it has been shown how the model creates a structured way of working, where human judgment and generative technology are part of a distributed and cognition-oriented interaction.

Through the fictitious case, it became clear how the model can be operationalised in a specific design task. From problem definition and prompting over validation and dissection to co-creation and finished solution, the case demonstrated the model's potential to support complex design development without locking in the process. Here, the AI functioned not only as a production tool but as a reflexive sparring partner that both challenged and refined the designer's decisions.

Theoretically, the model is rooted in concepts such as *designerly ways of knowing* (Cross, 2006), *reflection-in-action* (Schön, 1983), *situated agency* (Suchman, 1987) and *computational co-creativity* (Yannakakis & Togelius, 2014). Overall, AI Rocket positions itself as a middle ground between methodological model and thinking structure – it is not a fixed formula, but a scaffold that supports both cognition, experimentation and aesthetic assessment.

The model has both design strategic and pedagogical relevance. It can help strengthen the quality and pace of AI-enabled design development and at the same time serve as a framework in teaching, where it helps students understand and manage creative processes in a technological context. At the same time, the model paves the way for further development, e.g.

through the integration of feedback-based automation, bias detection or industry-adapted variants.

The AI Rocket model is thus a proposal for how to work methodically and critically with AI in creative subjects, without sacrificing intuition, aesthetic judgement and contextual sensitivity. It is part of a movement where design is not only a solution, but also a reflection – and where AI is not only an output, but also an epistemological counterpoint.
